More Design Patterns

- Marker interface
  - Label semantic attributes of a class

- Observer
  - A way of notifying change to a number of classes

- State
  - Alter an object's behavior when its state changes

- Visitor
  - Defines a new operation to a class without changing class
Marker Interface Pattern

Definition

Label semantic attributes of a class

Where to use & benefits

Need to indicate attribute(s) of a class
Allows identification of attributes of objects without assuming they are instances of any particular class
Marker Interface Pattern

Example

- Classes with desirable property GoodProperty
- Original
  - Store flag for GoodProperty in each class
- Using pattern
  - Label class using GoodProperty interface

Examples from Java

- Cloneable
- Serializable
public interface SafePet { } // no methods

class Dog implements SafePet { ... }
class Piranha { ... }

class d = new Dog();
class p = new Piranha();

if (d instanceof SafePet) ... // True
if (p instanceof SafePet) ... // False
Observer Pattern

Definition

Updates all dependents of object automatically once object changes state

Where to use & benefits

One change affects one or many objects
Many object behavior depends on one object state
Need broadcast communication
Maintain consistency between objects
Observers do not need to constantly check for changes
Observer Pattern

Example

- Multiple windows (views) for single document
- Original
  - Each window checks document
  - Window updates image if document changes
  - Think of window as asking “Are we there yet?”
- Using pattern
  - Each window registers as observer for document
  - Document notifies all of its observers when it changes
Observer Example

public interface Observer {
    public void update(Observable o, Object a)  // called when observed object o changes
}

public class Observable {
    protected void setChanged()  // changed
    protected void clearChanged()  // no change
    boolean hasChanged()  // return changed?

    void addObserver(Observer o)  // track observers
    void notifyObservers()  // notify if changed,
    void notifyObservers(Object a)  // then clear change
}
Observer Example

```java
public class MyWindow implements Observer {
    public openDoc(Observable doc) {
        doc.addObservers(this); // add window to list
    }
    public void update(Observable doc, Object arg) {
        redraw(doc); // display updated document
    }
}
public class MyDoc extends Observable {
    public void edit() {
        ... // edit document
        setChanged(); // mark change
        notifyObservers(arg); // invokes update()
    }
}
```
State Pattern

Definition
- Represent change in an object’s behavior using its member classes

Where to use & benefits
- Control states without many if-else statements
- Represent states using classes
- Every state has to act in a similar manner
- Simplify and clarify the program
State Pattern

Example

States representing finite state machine (FSM)

Original

- Each method chooses action depending on state
- Behavior may be confusing, state is implicit

Using pattern

- State interface defines list of actions for state
- Define inner classes implementing State interface
- Finite state machine instantiates each state and tracks its current state
- Current state used to choose action
public class FickleFruitVendor {
    boolean wearingHat;
    boolean isHatOn() { return wearingHat; }
    String requestFruit() {
        if (wearingHat) {
            wearingHat = false;
            return "Banana";
        } else {
            wearingHat = true;
            return "Apple";
        }
    }
}
State Example

public interface State {
    boolean isHatOn();
    String requestFruit();
}

public class WearingHat implements State;
public class NotWearingHat implements State;
State Example

public class FickleFruitVendor {
    State wearingHat = new WearingHat();
    State notWearingHat = new NotWearingHat();

    // explicitly track current state of Vendor
    State currentState = wearingHat;

    // behavior of Vendor depends on current state
    public boolean isHatOn() {
        return currentState.isHatOn();
    }

    public String requestFruit() {
        return currentState.requestFruit();
    }
}
class WearingHat implements State {
    boolean isHatOn() { return true; }
    String requestFruit() {
        currentState = notWearingHat; // change state
        return "Banana";
    }
}

class NotWearingHat implements State {
    boolean isHatOn() { return false; }
    String requestFruit() {
        currentState = wearingHat; // change state
        return "Apple";
    }
} // end class
Visitor Pattern

Definition

Define operations on elements of data structures without changing their classes

Where to use & benefits

Add operations to classes with different interfaces
Can modify operations on data structure easily
Encapsulate operations on elements of data structure
Decouples classes for data structure and algorithms
Crossing class hierarchies may break encapsulation
Visitor Pattern

Example

- Print elements in collection of objects

Original

- Iterator chooses action based on type of object
- Many if-else statements

Using pattern

- Visitor interface defines actions during visit
- Visitable interface allow objects to accept visit
- Action automatically selected by polymorphic functions through double dispatch
public void messyPrintCollection(Collection c) {
    for (Object o : c) {
        if (o instanceof String)
            System.out.println("{")+o.toString()+"}""); // add {
    else if (o instanceof Float)
            System.out.println(o.toString()+"f"); // add f
        else
            System.out.println(o.toString());
    }
}
Visitor Example

```java
public interface Visitor {
    public void visit(VisitableString s);
    public void visit(VisitableFloat f);
}

public interface Visitable {
    public void accept(Visitor v);
}
```
Visitor Example

public class VisitableString implements Visitable
{
    private String value;
    public VisitableString(String s) { value = s; }
    public String toString() { return value.toString(); }
    public void accept(Visitor v) { v.visit(this); }
}

public class VisitableFloat implements Visitable
{
    private Float value;
    public VisitableFloat(Float f) { value = f; }
    public String toString() { return value.toString(); }
    public void accept(Visitor v) { v.visit(this); }
}
public class PrintVisitor implements Visitor {
    public void visitCollection(Collection c) {
        for (Object o : c) {
            if (o instanceof Visitable)
                ((Visitable) o).accept(this);
            else
                System.out.println(o.toString());
        }
    }
    public void visit(VisitableString s) {
        System.out.println("{"+s.toString()+"}");
    }
    public void visit (VisitableFloat f) {
        System.out.println(f.toString() +"f");
    }
}
UML Class Diagram of Abstract Visitor
